Mathematics of Algorithm Complexity

Algorithm typically consists of loop and iteration structure
- complexity $\sim$ series summation

Method of calculating series summation
- general term formula $\sim$ exact result
- estimate the upper bound of summation $\sim$ approximate result

Algorithm may consist of recursive structure
- complexity $\sim$ recurrence relation

Methods of solving recurrence relation
- recurrence relation is simple: direct iteration + substitution iteration
- recurrence relation is complex: simplification + recursion tree
- general case: master theorem
**Sequence:** an ordered list of numbers; the numbers in this ordered list are called the “terms” of the sequence.
Concepts of Sequences and Series

**Sequence:** an ordered list of numbers; the numbers in this ordered list are called the “terms” of the sequence.

**Series:** the sum all the terms of a sequence; the resulting value, are called the “sum” or the “summation”.

Example. 1; 2; 3; 4 is a sequence, with terms “1”, “2”, “3”, “4”; the corresponding series is the sum “1 + 2 + 3 + 4”, and the value of the series is 10.
Concepts of Sequences and Series

**Sequence:** an ordered list of numbers; the numbers in this ordered list are called the “terms” of the sequence.

**Series:** the sum all the terms of a sequence; the resulting value, are called the “sum” or the “summation”.

**Example.** 1, 2, 3, 4 is a sequence, with terms “1”, “2”, “3”, “4”; the corresponding series is the sum “1 + 2 + 3 + 4”, and the value of the series is 10.

Next, we first recall three classical sequences.
Arithmetic Sequence

\[ a, a + d, \ldots, a + (n - 1)d \]

\[ a_i = a + (i - 1)d \]

**common difference** = \( d \neq 0 \)

Arithmetic Series

\[ S(n) = \sum_{i=1}^{n} a_i = \frac{n(a_1 + a_n)}{2} = \frac{n(2a + (n - 1)d)}{2} \]
Geometric Sequence

Geometric Sequence

\[ a, ar, \ldots, ar^{n-1} \]

\[ a_i = ar^{i-1} \]

common ratio \( = r \neq 1 \)

Geometric Series

\[
S(n) = \sum_{i=1}^{n} ar^{i-1} = a + ar + ar^2 + \cdots + ar^{n-1}
\]

\[
rS(n) = \sum_{i=1}^{n} ar^i = ar + ar^2 + ar^3 + \cdots + ar^n
\]

\[
\Rightarrow S(n) - rS(n) = a - ar^n \Rightarrow
\]

\[
S(n) = a \left( \frac{1 - r^n}{1 - r} \right) \quad \lim_{n \to \infty} S(n) = \frac{a}{1 - r}, |r| < 1
\]
Visualization of Geometric Series

\[ S(n) = \frac{1}{2} + \frac{1}{4} + \ldots \]

\[ S(n) = 1 + \frac{1}{2} + \frac{1}{4} + \frac{1}{8} + \ldots \]
Applications of Geometric Sequence

Geometric Series are among the simplest examples of infinite series with finite sums (although not all of them have this property).

Geometric series are used throughout mathematics, have important applications in physics, engineering, biology, economics, computer science, queueing theory, and finance.

- Repeating decimals (0.77777\cdots)
- Fractal geometry
- Zeno’s paradoxes
- Economics: the present value of an annuity
Harmonic Sequence

Harmonic Sequence (whose inverse forms an arithmetic sequence)

\[1, \frac{1}{2}, \ldots, \frac{1}{n}\]

\[a_i = \frac{1}{i}\]

Figure: Pythagoras
Calculation of Harmonic Series: Integral Test

\[ S(n) = \Theta(\ln n) \]
Calculation of Harmonic Series: Integral Test

\[ S(n) = \sum_{i=1}^{n} \frac{1}{i} > \int_{1}^{n+1} \frac{1}{x} \, dx = \ln(n + 1) \]

\[ S(n) = \Theta(\ln n) \]
Calculation of Harmonic Series: Integral Test

\[ S(n) = \sum_{i=1}^{n} \frac{1}{i} \]

Lower bound

\[ S(n) = \sum_{i=1}^{n} \frac{1}{i} > \int_{i=1}^{n+1} \frac{1}{x} dx = \ln(n + 1) \]

Upper bound

\[ S(n) = \sum_{i=1}^{n} \frac{1}{i} = 1 + \left( \frac{1}{2} + \cdots + \frac{1}{n} \right) < 1 + \int_{i=1}^{n} \frac{1}{x} dx = \ln n + 1 \]

\[ S(n) = \Theta(\ln n) \]
Interesting Properties of These Sequences

The middle term is the “mean” of its two neighbors
Interesting Properties of These Sequences

The middle term is the “mean” of its two neighbors

- arithmetic sequences

  \[
  \text{arithmetic mean:} \quad a_{i+1} = \frac{a_i + a_{i+2}}{2}
  \]
Interesting Properties of These Sequences

The middle term is the “mean” of its two neighbors

- arithmetic sequences

  arithmetic mean: $$a_{i+1} = \frac{a_i + a_{i+2}}{2}$$

- geometric sequences

  geometric mean: $$a_{i+1} = \sqrt{a_i \cdot a_{i+2}}$$
Interesting Properties of These Sequences

The middle term is the “mean” of its two neighbors

- **arithmetic sequences**

  \[
  \text{arithmetic mean: } a_{i+1} = \frac{a_i + a_{i+2}}{2}
  \]

- **geometric sequences**

  \[
  \text{geometric mean: } a_{i+1} = \sqrt{a_i \cdot a_{i+2}}
  \]

- **harmonic sequences**

  \[
  \text{harmonic mean: } a_{i+1} = \frac{2}{\frac{1}{a_i} + \frac{1}{a_{i+2}}}
  \]
Exact Series Summation

\[
\sum_{i=1}^{n} i2^{i-1} = \sum_{i=1}^{n} i(2^i - 2^{i-1}) \quad \text{//split terms}
\]

\[
= \sum_{i=1}^{n} i2^i - \sum_{i=1}^{n} i2^{i-1}
\]

\[
= \sum_{i=1}^{n} i2^i - \sum_{i=0}^{n-1} (i + 1)2^i \quad \text{//substitute subscripts}
\]

\[
= \sum_{i=1}^{n} i2^i - \sum_{i=0}^{n-1} i2^i - \sum_{i=0}^{n-1} 2^i \quad \text{//split terms}
\]

\[
= n2^n - (2^n - 1) = (n - 1)2^n + 1 \quad \text{//geometric series}
\]
Approximate Series Summation

**Amplification method**

1. \[ \sum_{i=1}^{n} a_i \leq n a_{\text{max}} \text{ (coarse)} \]

2. Assume \( \exists \ 0 < r < 1, \) s.t. \( \forall k \geq 0 \) the inequality \( a_{i+1}/a_i \leq r \) holds, we can amplify them to geometric series

\[
\sum_{i=0}^{n} a_i \leq \sum_{i=0}^{n} a_0 r^i = a_0 \frac{1 - r^n}{1 - r}
\]
Example of Amplification Method

Estimate the upper bound of $\sum_{i=1}^{n} \frac{i}{3^i}$

Solution.

$$a_i = \frac{i}{3^i}, a_{i+1} = \frac{i + 1}{3^{i+1}} \Rightarrow$$

$$\frac{a_{i+1}}{a_i} = \frac{1 \cdot i + 1}{3 \cdot i} \leq \frac{2}{3}$$

Apply the amplification method, we have:

$$\sum_{i=1}^{n} \frac{i}{3^i} < \sum_{i=1}^{\infty} \frac{1}{3} \left(\frac{2}{3}\right)^{i-1} = \frac{1}{3} \frac{1}{1 - \frac{2}{3}} = 1$$
Algorithm 1: BinarySearch($A, l, r, x$)

Input: $A[l, r]$, target element $x$

Output: $j$

1: $l \leftarrow 1$, $r \leftarrow n$;
2: \textbf{while} $l \leq r$ \textbf{do}
3: \hspace{1em} $m \leftarrow \lfloor (l + r)/2 \rfloor$;
4: \hspace{1em} \textbf{if} $A[m] = x$ \textbf{then return} $m$;  // $x$ is the median
5: \hspace{1em} \textbf{else if} $A[m] > x$ \textbf{then} \hspace{1em} $r \leftarrow m - 1$;
6: \hspace{1em} \textbf{else} \hspace{1em} $l \leftarrow m + 1$;
7: \hspace{1em} \textbf{end}
8: \textbf{return} 0
Demo of Binary Search

1st compare: 3.5 < 4

2nd compare: 3.5 > 2

3rd compare: 3.5 > 3
Input Size $n$

Ideal case. $n = 2^k - 1$

There are $2n + 1$ possibilities of $x$:

- $x$ in the array: $n$
- $x$ not in the array: fall into $n + 1$ intervals
**Input Size** $n$

**Ideal case.** $n = 2^k - 1$

There are $2n + 1$ possibilities of $x$:

- $x$ in the array: $n$
- $x$ not in the array: fall into $n + 1$ intervals

Q. Why we call $n = 2^k - 1$ as ideal case?
Input Size $n$

**Ideal case.** $n = 2^k - 1$

There are $2n + 1$ possibilities of $x$:
- $x$ in the array: $n$
- $x$ not in the array: fall into $n + 1$ intervals

Q. Why we call $n = 2^k - 1$ as ideal case?

A. Because the size of sub-problem is still of the form $2^i - 1$
Number of input $x$ that requires $t$ times compare ($n = 7, k = 3$)

$t = 1 : 1$

$t = 2 : 2$

$t = 3 : 4$

- for $t \in [k - 1]$, \# possible input elements that requires $t$ times compares is $2^{t-1}$
- for $t = k$, \# possible input elements that requires $t$ times compares is $2^{k-1} + (n + 1)$
Average-case complexity of Binary Search

Let \( n = 2^k - 1 \), assume \( x \) appears at each position with the same probability:

\[
T(n) = \frac{1}{2n+1} \left( \sum_{t=1}^{k-1} t2^{t-1} + k(2^{k-1} + n + 1) \right)
\]

\[
= \frac{1}{2n+1} \left( \sum_{t=1}^{k} t2^{t-1} + k(n + 1) \right)
\]

\[
= \frac{1}{2n+1} \left( (k - 1)2^k + 1 + k(n + 1) \right) // use previous result
\]

\[
= \frac{k2^k - 2^k + 1 + k2^k + k}{2^{k+1} - 1}
\]

\[
= \frac{k(2^{k+1} - 1) + 2^k + 1 + 2k}{2^{k+1} - 1} \approx k + \frac{1}{2} = \Theta(\log n)
\]
1. Sequences and Series Summation

2. Recurrence Relation and Algorithm Analysis
   - Approach 1: Direct Iteration
   - Approach 2: Simplification-then-Iteration
   - Approach 3: Recursion Tree

3. Master Theorem and Its Proof

4. Application of Master Theorem
Motivation

Recursion and Iteration are two commonly used programming paradigm

Solution to a problem is obtained by combining solutions to subproblems of smaller size.

In this case, time complexity functions can be expressed as recurrence relations.

How to solve recurrence relations?
**Definition 1 (Recurrence Relation)**

Let \( a_0, a_1, \ldots, a_n \) be a sequence, shorthand as \( \{a_n\} \). A recurrence relation defines each term of a sequence using preceding term(s), and always state the initial term of the sequence.

*Recurrence relation captures the dependence of a term to its preceding terms.*

**Solution.** Given recurrence relation for a sequence \( \{a_n\} \) together with some initial values, compute the general term formula of \( a_n \).

- **general term formula:** a function of \( n \), without involvement of other terms
Example of Recurrence Relation: Fibonacci Number

Fibonacci number:
1, 1, 2, 3, 5, 8, 13, 21, 34, 55, ...  

Recurrence relation:
\[ f_n = f_{n-1} + f_{n-2} \]

Initial value: \( f_0 = 1, f_1 = 1 \)
Example of Recurrence Relation: Fibonacci Number

Fibonacci number:
1, 1, 2, 3, 5, 8, 13, 21, 34, 55, \ldots

Recurrence relation:
\[ f_n = f_{n-1} + f_{n-2} \]

Initial value: \( f_0 = 1, \ f_1 = 1 \)

Figure: Fibonacci
Next, we introduce three methods for solving recurrence relation.

\[ f_n = \frac{1}{\sqrt{5}} \left(\frac{1 + \sqrt{5}}{2}\right)^{n+1} - \frac{1}{\sqrt{5}} \left(\frac{1 - \sqrt{5}}{2}\right)^{n+1} \]
Steps of Direct Iteration

When the recurrence relation is simple, i.e., $F(n)$ only relies on $F(n-1)$, we use direct iteration.

1. Continuously substitute the “right part” of formula with the “right right part”
2. After each substitution, a new term emerged in the series as $n$ decreases
3. Stop substitution until reaching the initial values
4. Calculate the series with the initial values
5. Use mathematical induction to check the correctness of the solution

Remark. When the correctness is evident, mathematical induction is not necessary. It is useful for testing if your guess is correct.
Example: Hanoi Tower Problem

Origin. When creating the world, Brahma also built three diamond rods and 64 golden disks of different sizes. At the beginning, the disks place in ascending order of size on one rod, the smallest at the top, thus making a conical shape. Brahmin priests have been moving these disks from one rod to another rod in accordance with the immutable rules of Brahma since that time. When the last move is completed, the world will end.
Problem as a Puzzle

Problem Abstract. There are three rods (labeled as $A, B, C$) with $n$ of disks of different sizes. At the beginning, the disks in a neat stack in ascending order of size on rod $A$. The objective of figuring out the minimum number of moves $T(n)$ required to move the entire stack to rod $C$, obeying the following rules:

- Only one disk can be moved at a time.
- Each move consists of taking the upper disk from one of the stacks and placing it on top of another stack or on an empty rod.
- No larger disk may be placed on top of a smaller disk.

Example. $n = 1$, $T(1) = 1$; $n = 2$, $T(2) = 3$; $n = 3$, $T(3) = 7$; general form $T(n) = ?$.
Problem as a Puzzle

Problem Abstract. There are three rods (labeled as $A, B, C$) with $n$ of disks of different sizes. At the beginning, the disks in a neat stack in ascending order of size on rod $A$. The objective of figure out the minimum number of moves $T(n)$ required to move the entire stack to rod $C$, obeying the following rules:

- Only one disk can be moved at a time.
- Each move consists of taking the upper disk from one of the stacks and placing it on top of another stack or on an empty rod.
- No larger disk may be placed on top of a smaller disk.

Example. $n = 1, T(1) = 1; n = 2, T(2) = 3; n = 3, T(3) = 7;$
Problem as a Puzzle

Problem Abstract. There are three rods (labeled as $A$, $B$, $C$) with $n$ of disks of different sizes. At the beginning, the disks in a neat stack in ascending order of size on rod $A$. The objective of figure out the minimum number of moves $T(n)$ required to move the entire stack to rod $C$, obeying the following rules:

- Only one disk can be moved at a time.
- Each move consists of taking the upper disk from one of the stacks and placing it on top of another stack or on an empty rod.
- No larger disk may be placed on top of a smaller disk.

Example. $n = 1$, $T(1) = 1$; $n = 2$, $T(2) = 3$; $n = 3$, $T(3) = 7$;

general form $T(n) =$?
Recursive Algorithm for Hanoi Tower

Algorithm 2: Hanoi($A, C, n$) // move $n$ disks from $A$ to $C$

<table>
<thead>
<tr>
<th>Input:</th>
<th>$A(n), B(0), C(0)$</th>
</tr>
</thead>
<tbody>
<tr>
<td>Output:</td>
<td>$A(0), B(0), C(n)$</td>
</tr>
</tbody>
</table>

1. if $n = 1$ then move $(A, C)$; //one disk from $A$ to $C$
2. else
3. Hanoi($A, B, n - 1$);
4. move $(A, C)$;
5. Hanoi($B, C, n - 1$)
6. end

Let $T(n)$ be the number of moves required to move $n$ disks

- $T(n) = 2T(n - 1) + 1$
- $T(1) = 1$
Complexity Analysis: Direct Iteration

\[
T(n) = 2T(n - 1) + 1 \\
T(1) = 1
\]
\[
\Rightarrow T(n) = 2^n - 1
\]
Complexity Analysis: Direct Iteration

\[
T(n) = 2T(n - 1) + 1
\]
\[
T(1) = 1
\]
\[
\{ \Rightarrow T(n) = 2^n - 1 \}
\]

\[
T(n) = 2T(n - 1) + 1
\]
\[
= 2(2T(n - 2) + 1) + 1
\]
\[
= 2^2 T(n - 2) + 2 + 1
\]
\[
= \ldots
\]
\[
= 2^{n-1} T(1) + 2^{n-2} + \cdots + 2 + 1 \quad \text{//reaching the initial terms}
\]
\[
= 2^{n-1} \cdot 1 + 2^{n-1} - 1 \quad \text{//substitute with initial values}
\]
\[
= 2^n - 1
\]
More about Hanoi Tower

Is there a better algorithm?
Is there a better algorithm?

No! Tower of Hanoi is an intractable problem, no polynomial time algorithm is known.
More about Hanoi Tower

Is there a better algorithm?
No! Tower of Hanoi is an intractable problem, no polynomial time algorithm is known.

Q. 1 move/s, how many times needed to move 64 disks?
Is there a better algorithm?

No! Tower of Hanoi is an intractable problem, no polynomial time algorithm is known.

Q. 1 move/s, how many times needed to move 64 disks?
A. 500 billion years! Bad news for algorithm but good news to the world!
Example: Iterated Algorithm for Insertion Sort

**Algorithm 3: InsertionSort**(\(A, n\))

**Input:** unsorted \(A[n]\)

**Output:** \(A[n]\) in ascending order

1: \(\text{for } i \leftarrow 2 \text{ to } n \text{ do}\)
2: \(j \leftarrow i\)  \hspace{1cm} //insert \(A[i]\);
3: \(\text{while } j > 0 \text{ and } A[j - 1] > A[j] \text{ do}\)
4: \(\text{swap } A[j - 1] \text{ and } A[j];\)
5: \(j \leftarrow j - 1;\)
6: \(\text{end}\)
7: \(\text{end}\)
Worse-case Complexity

Basic computer step. element compare

Input size. \( n \)

\[
\begin{align*}
W(n) &= W(n - 1) + (n - 1) \\
W(1) &= 0 \\
\end{align*}
\]

\[\Rightarrow W(n) = n(n - 1)/2\]

- When inserting the \( i \)-th element, algorithm compares it with the first \( i - 1 \) sorted elements; the maximum number of compare is \( i - 1 \).
Solve Recurrence Relation by Direct Iteration

\[ W(n) = W(n - 1) + n - 1 \]
\[ = (W(n - 2) + n - 2) + n - 1 \]
\[ = W(n - 2) + n - 2 + n - 1 \]
\[ = \ldots \]
\[ = W(1) + 1 + 2 + \cdots + (n - 2) + (n - 1) / \text{reach the initial term} \]
\[ = 1 + 2 + \cdots + (n - 2) + (n - 1) / \text{substitute with initial value} \]
\[ = n(n - 1)/2 \]
Mathematical induction is a mathematical proof technique to prove that a property $P(n)$ holds for every natural number $n \in \mathbb{N}$.

Mathematical induction proves that we can climb as high as we like on a ladder, by proving that we can climb onto the bottom rung (the basis) and that from each rung we can climb up to the next one (the step). — Concrete Mathematics
Template of Mathematical Induction

The method of induction requires two facts to be proved.

**Induction basis:** Prove the property holds for number 0.

**Induction step**

1. Prove that if the property holds for one natural number \( n \), then it holds for the next natural number \( n + 1 \)

\[
P(0) = 1
\]
\[
\forall n, P(n) = 1 \Rightarrow P(n + 1) = 1
\]
\[
n = 0, P(0) \Rightarrow P(1); n = 1, P(1) \Rightarrow P(2) \ldots
\]

2. Prove that the property holds for all natural number \( k < n \), then it also holds for \( n \).

\[
P(0) = 1
\]
\[
\forall k < n, P(k) = 1 \Rightarrow P(n) = 1
\]
\[
n = 1, P(0) = 1 \Rightarrow P(1) = 1;
\]
\[
n = 2, P(0) = 1 \land P(1) = 1 \Rightarrow P(2) = 1 \ldots
\]
Comparsion Between Two Types of Mathematics Induction

Induction basis is same: $P(0) = 1$

Induction step is different

Logic reasoning:

1. Type 1 induction: $P(0) = 1 \Rightarrow P(1) = 1 \Rightarrow P(2) = 1$

2. Type 2 induction:
   
   $P(0) = 1 \Rightarrow P(0) = 1 \land P(1) = 1 \Rightarrow P(0) = 1 \land P(1) = 1 \land P(2) = 1 \Rightarrow P(0) = 1 \land P(1) = 1 \land P(2) = 1 \land P(3) = 1$

Think. The intutions are same, when to apply which?

- Type 1 (loose coupling): the property of next number only depends on its nearest preceding
- Type 2 (tight coupling): the property of next number depends on all its precedings
Remarks on Mathemetic Induction

These two steps establish the property $P(n) = 1$ for every natural number $n = 0, 1, 2, 3$.  

©Yu Chen
Remarks on Mathematic Induction

These two steps establish the property $P(n) = 1$ for every natural number $n = 0, 1, 2, 3$.

- The base case does not necessarily begin with $n = 0$. It can begin with any natural number $n_0$, establishing the truth of $P(n) = 1$ holds for all $n \geq n_0$. 
Remarks on Mathematic Induction

These two steps establish the property $P(n) = 1$ for every natural number $n = 0, 1, 2, 3$.

- The base case does not necessarily begin with $n = 0$. It can begin with any natural number $n_0$, establishing the truth of $P(n) = 1$ holds for all $n \geq n_0$.

- The method can be extended to structural induction to prove statements about more general well-founded structures, such as trees (widely used in mathematical logic and computer science).
Correctness of Solution: Mathematical Induction

Proposition. $W(n) = \frac{n(n - 1)}{2}$ is the general term formula for recurrence relation

$$
\begin{align*}
W(n) &= W(n - 1) + n - 1 \\
W(1) &= 0
\end{align*}
$$
Correctness of Solution: Mathematical Induction

Proposition. \( W(n) = \frac{n(n - 1)}{2} \) is the general term formula for recurrence relation

\[
\begin{cases}
W(n) = W(n - 1) + n - 1 \\
W(1) = 0
\end{cases}
\]

Method: Mathematical Induction

1. Basis: \( n = 1 \), \( W(1) = 1 \times (1 - 1)/2 = 0 \)
2. Induction step: \( P(n) = 1 \Rightarrow P(n + 1) = 1 \):

\[
W(n + 1) = W(n) + n
= n(n - 1) + n
= n((n - 1)/2 + 1) = n(n + 1)/2
\]
Substitution-then-Iteration

When \( n \) itself is a function of another variable, say, \( k \), and \( k \) decreases 1 after each iteration, we first substitute \( n \) by the function of \( k \), then apply the iteration approach over \( k \).

1. Transform the recursive formula about \( n \) to recursive formula about \( k \)

2. Iterate over \( k \)

3. Transform the general term formula about \( k \) back to general term formula about \( n \)
Algorithm 4: MergeSort($A, n$)

**Input:** unsorted $A[n]$

**Output:** sorted $A[n]$ in ascending order

1: $l \leftarrow 1$, $r \leftarrow n$;
2: if $l < r$ then
3: \[ k \leftarrow \lfloor (l + r)/2 \rfloor; \]
4: MergeSort($A, l, k$);
5: MergeSort($A, k + 1, r$);
6: Merge($A, p, k, r$)
7: end
Example of Substitution-and-Iteration

Assume $n = 2^k$, the recurrence relation is:

\[
\begin{aligned}
W(n) &= 2W(n/2) + n - 1 \\
W(1) &= 0
\end{aligned}
\]

- $n - 1$ is the cost of merge

Substitution: $n \rightarrow 2^k$

\[
\begin{aligned}
W(2^k) &= 2W(2^{k-1}) + 2^k - 1 \\
W(2^0 = 1) &= 0
\end{aligned}
\]
Substitution

\[ W(n) \]
\[ = 2W(2^{k-1}) + 2^k - 1 \quad // \text{substitute and iterate on } k \]
\[ = 2(2W(2^{k-2}) + 2^{k-1} - 1) + 2^k - 1 \quad // \text{1st round iteration} \]
\[ = 2^2W(2^{k-2}) + 2^k - 2 + 2^k - 1 \quad // \text{2nd round iteration} \]
\[ = 2^2(2W(2^{k-3}) + 2^{k-2} - 1) + 2^k - 2 + 2^k - 1 \]
\[ = \ldots \]
\[ = 2^kW(2^0 = 1) + k2^k - (2^{k-1} + 2^{k-2} + \cdots + 2 + 1) \]
\[ = k2^k - 2^k + 1 \]
\[ = n \log n - n + 1 \quad // \text{substitute back} \]
Motivation

- Basic approach for solving recurrence relation is iteration

- When the original recurrence relation is complex, we need simplification
  - transform high order equation to one order equation, then substitute
Example of QuickSort

Recap of QuickSort

Suppose the elements in $A[n]$ are distinct, set $l \leftarrow 1$, $r \leftarrow n$, partition $A[l \ldots r]$ with the first element $A[1] = x$, such that
- elements less than $x$ are stored in $A[l \ldots k - 1]$
- elements greater than $x$ are stored in $A[k + 1 \ldots r]$
- $A[1]$ is placed in $A[k]$

Sort $A[l \ldots k - 1]$ and $A[k + 1 \ldots r]$ recursively

Overall complexity.
- complexity of subproblems
- complexity of partition
Input and Subproblem Size

According to the final position of the first element $x$ in the resulting sorted array, we can break input to $n$ cases

<table>
<thead>
<tr>
<th>final position of $x$</th>
<th>size of subproblem-1</th>
<th>size of subproblem-2</th>
</tr>
</thead>
<tbody>
<tr>
<td>1</td>
<td>0</td>
<td>$n - 1$</td>
</tr>
<tr>
<td>2</td>
<td>1</td>
<td>$n - 2$</td>
</tr>
<tr>
<td>3</td>
<td>2</td>
<td>$n - 3$</td>
</tr>
<tr>
<td>...</td>
<td>...</td>
<td>...</td>
</tr>
<tr>
<td>$n - 1$</td>
<td>$n - 2$</td>
<td>1</td>
</tr>
<tr>
<td>$n$</td>
<td>$n - 1$</td>
<td>0</td>
</tr>
</tbody>
</table>

- For each input, the number of compares required for partition is exactly $n - 1$ (think why?)
Summation of Complexity

\[
T(0) + T(n - 1) + n - 1 \\
T(1) + T(n - 2) + n - 1 \\
T(2) + T(n - 3) + n - 1 \\
\vdots \\
T(n - 1) + T(0) + n - 1
\]

Summation: \(2(T(1) + \cdots + T(n - 1)) + n(n - 1)\)
**Average Complexity of QuickSort**

**Assumption.** The first element $x$ finally appears at each position with equal probability:

$$T(n) = \frac{2}{n} \sum_{i=1}^{n-1} T(i) + O(n), \quad n \geq 2$$

- $T(1) = 0$
- $T(0) = 0$

**Observation and Idea**

- The recurrence relation is complex: $n$-th term depends on all preceding terms $\sim$ direct iteration would be very complex
- **Idea:** Simplify the complex equation, then iterate
Simplification via Subtraction

Rewrite and iterate once to obtain two recurrence relations, then try to simplify the terms of the right side.

\[ T(n) = \frac{2}{n} \sum_{i=1}^{n-1} T(i) + n - 1 \]

\[ nT(n) = 2 \sum_{i=1}^{n-1} T(i) + n(n - 1) \]

\[ (n - 1)T(n - 1) = 2 \sum_{i=1}^{n-2} T(i) + (n - 1)(n - 2) \]
Simplification via Subtraction

Subtraction

\[ nT(n) - (n - 1)T(n - 1) = 2T(n - 1) + 2(n - 1) \]

Simplification

\[ nT(n) = (n + 1)T(n - 1) + \Theta(n) \]

Rewrite

\[ \frac{T(n)}{n + 1} = \frac{T(n - 1)}{n} + \frac{\Theta(n)}{n(n + 1)} = \frac{T(n - 1)}{n} + \frac{\Theta(1)}{n + 1} \]
Iteration

\[
\frac{T(n)}{n+1} = \frac{T(n-1)}{n} + \frac{\Theta(1)}{n+1} = \ldots
\]

\[
= \Theta(1) \left( \frac{1}{n+1} + \frac{1}{n} + \ldots + \frac{1}{3} \right) + \frac{T(1)}{2} //\text{reach the initial term}
\]

\[
= \Theta(1) \left( \frac{1}{n+1} + \frac{1}{n} + \ldots + \frac{1}{3} \right) //\text{substitute with initial value}
\]

\[
= \Theta(\ln n)
\]

\[
T(n) = \Theta(n \log n)
\]
Concept of Recursion Tree

When $F(n)$ relies on several non-consecutive preceding terms, we could try solving the recurrence relation using recursion tree.

- Recursion tree is the model of recursive computation, also the iteration of recurrence relation
- The generation of recursion tree is same as that of recursion process
- The nodes on the recursion tree is exactly the terms in the series of recursion
- The summation of all nodes (including the internal and leaf nodes) on the recursion tree is the solution to the recurrence relation
Representation of Iteration in Recursion Tree

Recursion tree is the model of recursion ⇒ closely related to solving for recurrence relation

Assume the recurrence relation is as below:

\[ T(n) = T(n_1) + \cdots + T(n_t) + f(n), |n_1|, \ldots, |n_t| < |m| \]

- \( T(n_1), \ldots, T(n_t) \): function items
- \( f(n) \): dividing cost + merging cost

How to represent \( T(n) \) on the recursion tree? How to represent the corresponding recursion?
Visualization of Recursion Tree

$T(n)$

summation of all nodes
values are equal
1st recursion

$f(n)$

$T(n_1)$  $T(n_2)$  $T(n_3)$  ...  $T(n_t)$

root node is the combine and divide cost
each leaf node is a function term
Recurrent relation for MergeSort

\[
\begin{cases}
T(n) = 2T(n/2) + (n - 1) \\
T(2) = 1 \\
T(1) = 0 \\
(n - 1)
\end{cases}
\]
The Generation Rules of Recursion Tree

1. At the very beginning, there is only the root node in the recursion tree, whose value is $T(n)$

2. Repeat the following steps:
   - represent the function term $T(n)$ in the leaf node as a 2-level subtree
   - replace the leaf node with this subtree

3. Continue the generation of recursion tree until there is no function term in the tree.
   - Reaching the leaf nodes — initial values
Demo of Recursion Tree Generation

\[ T(n) = \begin{cases} \frac{n}{2} & \text{if } n \leq 1 \\ \frac{n}{2} + \frac{n}{4} + \frac{n}{4} & \text{if } n > 1 \end{cases} \]
The Whole Recursion Tree

\[ n - 1 \]

\[ \frac{n}{2} - 1 \quad \frac{n}{2} - 1 \]

\[ \frac{n}{4} - 1 \quad \frac{n}{4} - 1 \quad \frac{n}{4} - 1 \quad \frac{n}{4} - 1 \]

\[ \ldots \ldots \]

\[ 1 \quad \ldots \ldots \quad 1 \]

\[ 0 \quad 0 \quad \ldots \ldots \quad 0 \quad 0 \]

\[ n - 1 \]

\[ n - 2 \]

\[ n - 4 \]

\[ n - 2^{k-1} \]
Calculate the Sum of Recursion Tree

\[
\begin{align*}
T(n) &= 2T(n/2) + n - 1, n = 2^k \\
T(1) &= 0
\end{align*}
\]

\[
T(n) = (n - 1) + (n - 2) + \cdots + (n - 2^{k-1})
\]

\[
= kn - (2^k - 1) \quad // k = \log n
\]

\[
= n \log n - n + 1
\]
Application of Recursion Tree

Compute the general term formula of

\[ T(n) = T(n/3) + T(2n/3) + n \]

The rates that different routes reach the initial value are different

- the left route is fastest – estimate the lower bound
- the right route is slowest – estimate the upper bound
Solving by Summation

Recurrence relation: \( T(n) = T(n/3) + T(2n/3) + n \)

The depth of recursion tree is \( k \), the sum of each level is \( O(n) \)

- Estimate the longest route to calculate for the upper bound

\[
n \left( \frac{2}{3} \right)^k = 1 \Rightarrow \left( \frac{3}{2} \right)^k = n \Rightarrow k = \log_{3/2} n
\]

\[
T(n) < \log_{3/2} n \times n = O(n \log n)
\]

- Estimate the shortest route to calculate the lower bound

\[
T(n) > \log_3 n \times n = \Omega(n \log n)
\]

Putting all the above together, \( T(n) = \Theta(n \log n) \)
Remark

For the sake of simplicity, the leaf nodes that represent initial values are not included in the summation.

- The initial values usually cannot be represented by $f(n)$.
- The initial values are usually constants, such as 0 or 1, and thus they can be easily calculated separately.
1 Sequences and Series Summation

2 Recurrence Relation and Algorithm Analysis
   - Approach 1: Direct Iteration
   - Approach 2: Simplification-then-Iteration
   - Approach 3: Recursion Tree

3 Master Theorem and Its Proof

4 Application of Master Theorem
Application of Master Theorem

Solving recurrence relation

\[ T(n) = aT(n/b) + f(n) \]

- \( a \): the number of subproblems after dividing
- \( n/b \): the size of subproblems
- \( f(n) \): the cost of dividing and merging subproblems

Examples

- binary search: \( T(n) = T(n/2) + 1 \)
- merge sort: \( T(n) = 2T(n/2) + n - 1 \)
Master Theorem

Let $a \geq 1$, $b \geq 1$ be constants, $T(n)$ and $f(n)$ be functions, and

$$T(n) = aT(n/b) + f(n)$$

1. if $\exists \varepsilon > 0$ s.t. $f(n) = O(n^{(\log_b a) - \varepsilon})$, then:

$$T(n) = \Theta(n^{\log_b a})$$

2. if $f(n) = \Theta(n^{\log_b a})$, then:

$$T(n) = \Theta(n^{\log_b a} \log n)$$

3. if $\exists \varepsilon > 0$ s.t. $f(n) = \Omega(n^{(\log_b a) + \varepsilon})$, and $\exists r < 1$ s.t. for all $n$ (can be relaxed to for sufficiently large $n$) the inequality $af(n/b) \leq rf(n)$ holds, then:

$$T(n) = O(f(n))$$
How to prove the master theorem?
Direct Iteration

\[ T(n) = aT(n/b) + f(n) \]

For the sake of convenience, let \( n = b^k \)

\[ T(n) = aT \left( \frac{n}{b} \right) + f(n) \]
\[ = a \left( aT \left( \frac{n}{b^2} \right) + f \left( \frac{n}{b} \right) \right) + f(n) \]
\[ = a^2 T \left( \frac{n}{b^2} \right) + af \left( \frac{n}{b} \right) + f(n) \]
\[ = \ldots \]
Result of Iteration

\[ = a^k T \left( \frac{n}{b^k} \right) + a^{k-1} f \left( \frac{n}{b^{k-1}} \right) + \cdots + a f \left( \frac{n}{b} \right) + f(n) \]

\[ = a^k T(1) + \sum_{j=0}^{k-1} a^j f \left( \frac{n}{b^j} \right) \quad \text{//reach the initial term} \]

\[ = c_1 n \log_b a + \sum_{j=0}^{k-1} a^j f \left( \frac{n}{b^j} \right) \quad \text{//assume } T(1) = c_1 \]

\[ k = \log_b n = \log_b a \cdot \log_a n \]

- the first term is the total costs of all subproblems
- the second term is the total costs of all dividing and merging steps
Corresponding Recursion Tree

\[ n \]

\[ \frac{n}{b} \]

\[ \frac{n}{b^2} \]

branching factor \( a \)

depth \( \log_b n \)

width \( a^{\log_b n} = n^{\log_b a} \)
Explaining the Meaning of Recursion Tree

$a$: branching factor

$b$: the size of subproblems decreases by a factor of $b$ with each level of recursion

$k = \log_b n$: reaches the base case after $k$ levels, the height of the recursion tree

the $j$th level of the tree is made up of $a^j$ subproblems, each of size $n/b^j$
Case 1

\[ \exists \varepsilon > 0 \text{ s.t. } f(n) = O(n^{(\log_b a) - \varepsilon}) \]

\[ T(n) = c_1 n^{\log_b a} + O \left( \sum_{j=0}^{(\log_b n)-1} a^j \left( \frac{n}{b^j} \right)^{(\log_b a) - \varepsilon} \right) \] //substitute with premise

\[ = c_1 n^{\log_b a} + O \left( n^{(\log_b a) - \varepsilon} \sum_{j=0}^{(\log_b n)-1} \frac{a^j}{(b^{(\log_b a) - \varepsilon})^j} \right) \] //move sum irrelevant terms outside
Case 1: Continue to Simplify

\[
\frac{1}{((b \log_b a) - \varepsilon)^j} = \frac{b^j}{(b \log_b a)^j} = \frac{b^j}{a^j}
\]

\[
= c_1 n^{\log_b a} + O \left( n^{(\log_b a) - \varepsilon} \sum_{j=0}^{\log_b n - 1} \frac{a^j}{(b^{(\log_b a) - \varepsilon})^j} \right) \quad //\text{simplify}
\]

\[
= c_1 n^{\log_b a} + O \left( n^{(\log_b a) - \varepsilon} \sum_{j=0}^{\log_b n - 1} (b^\varepsilon)^j \right) \quad //\text{geometric series}
\]

\[
= c_1 n^{\log_b a} + O \left( n^{(\log_b a) - \varepsilon} \frac{b^{\varepsilon \log_b n} - 1}{b^\varepsilon - 1} \right) \quad //\text{ignore the constants}
\]

\[
= c_1 n^{\log_b a} + O \left( n^{(\log_b a) - \varepsilon} n^\varepsilon \right) = \Theta(n^{\log_b a})
\]
Case 2

\[ f(n) = \Theta(n^{\log_b a}) \]

\[ T(n) = c_1 n^{\log_b a} + \sum_{j=0}^{\log_b n - 1} a^j f \left( \frac{n}{b^j} \right) \]

\[ = c_1 n^{\log_b a} + \Theta \left( n^{\log_b a} \sum_{j=0}^{(\log_b n) - 1} a^j \left( \frac{n}{b^j} \right)^{\log_b a} \right) \]

\[ = c_1 n^{\log_b a} + \Theta(n^{\log_b a} \log n) = \Theta(n^{\log_b a} \log n) \]
Case 3

\[ \exists \varepsilon > 0, f(n) = \Omega(n^{(\log_b a) + \varepsilon}) \]  

\[ a f(n/b) \leq r f(n) \] \hspace{1cm} (1) \hspace{1cm} (2)

Repeatedly apply condition (2)

\[ a^j f \left( \frac{n}{b^j} \right) \leq a^{j-1} r f \left( \frac{n}{b^{j-1}} \right) \leq \cdots \leq r^j f(n) \]

\[ T(n) = c_1 n^{\log_b a} + \sum_{j=0}^{(\log_b n)-1} a^j f \left( \frac{n}{b^j} \right) \]

\[ \leq c_1 n^{\log_b a} + \sum_{j=0}^{(\log_b n)-1} r^j f(n) \]
Case 3 (continue)

\[ T(n) \leq c_1 n^{\log_b a} + \sum_{j=0}^{(\log_b n) - 1} r^j f(n) \]

\[ = c_1 n^{\log_b a} + f(n) \frac{r^{(\log_b n) - 1}}{r - 1} \quad \text{//geometric series with } r < 1 \]

\[ = c_1 n^{\log_b a} + \Theta(f(n)) \]

Condition 1 \( \Rightarrow \) order \((f(n)) \geq \text{order}(n^{\log_b a}) \)

\[ = \Theta(f(n)) \]

Condition 2 is used to prove the coefficient of \( f(n) \) is finite.
Simplified Form of Master Theorem

Define $h(n) = n^{\log_b a}$, we re-state master theorem as below:

$$T(n) = \begin{cases} 
\Theta(h(n)) & \text{if } f(n) = o(h(n)) \\
\Theta(h(n) \log n) & \text{if } f(n) = \Theta(h(n)) \\
O(f(n)) & \text{if } f(n) = \omega(h(n)) \\
\& \exists \ r < 1 \ \text{s.t.} \ af(n/b) < rf(n)
\end{cases}$$
1. Sequences and Series Summation

2. Recurrence Relation and Algorithm Analysis
   - Approach 1: Direct Iteration
   - Approach 2: Simplification-then-Iteration
   - Approach 3: Recursion Tree

3. Master Theorem and Its Proof

4. Application of Master Theorem
Example 1 of Solving Recurrence Relation

Compute the general term formula of recurrence relation:

\[ T(n) = 9T(n/3) + n \]

Applying the master theorem

- \( a = 9, \ b = 3, \ h(n) = n^2, \ \varepsilon = 1; \)
- \( f(n) = n, \ n^{\log_3 9} = n^2, \ f(n) = O(n^{\log_3 9 - 1}) = o(n^2) \)

Master theorem (case 1) \( \Rightarrow T(n) = \Theta(n^2) \)
Example 2 of Solving Recurrence Relation

Compute the general term formula of recurrence relation:

\[ T(n) = T(2n/3) + 1 \]

Applying the master theorem

- \( a = 1, \ b = 3/2, \ h(n) = n^{\log_b a} = n^0 = 1; \)
- \( f(n) = 1, \ n^{\log_{3/2} 1} = n^0 = 1, \ f(n) = \Theta(1) \)

Master theorem (case 2) \( \Rightarrow T(n) = \Theta(\log n) \)
Example 3 of Solving Recurrence Relation

Compute the general term formula of recurrence relation:

$$T(n) = 3T(n/4) + n \log n$$

Applying the master theorem

- $a = 3$, $b = 4$, $h(n) = n^{\log_4 3}$;
- $f(n) = n \log n = \Omega(n^{\log_4 3+\varepsilon}) \approx \Omega(n^{0.793+\varepsilon})$, choose $\varepsilon = 0.2$
- Check addition condition $af(n/b) \leq rf(n)$ holds for all $n$.
  - Test $f(n) = n \log n \Rightarrow af(n/b) = 3(n/4) \log(n/4) \leq rn \log n$ holds for some $r < 1$.
  - Choose $r = 3/4 < 1$, this inequality holds for all $n$.

Master theorem (case 3) $\Rightarrow T(n) = \Theta(f(n)) = \Theta(n \log n)$
Binary search. \( T(n) = T(n/2) + 1, \ T(1) = 1 \)

\[ a = 1, \ b = 2, \ h(n) = n^{\log_2 1} = 1, \ f(n) = 1 \]

Master theorem (case 2) \( \Rightarrow \ T(n) = \Theta(\log n) \)

---

Merge sort. \( T(n) = 2T(n/2) + 1, \ T(1) = 0 \)

\[ a = 2, \ b = 2, \ h(n) = n^{\log_2 2} = n, \ f(n) = n - 1 \]

Master theorem (case 2) \( \Rightarrow \ T(n) = \Theta(n \log n) \)
Cases that Master Theorem is not Applicable

Example. Compute the general term formula of

\[ T(n) = 2T(n/2) + n \log n \]

Apply master theorem. \( a = b = 2, \ h(n) = n^{\log_b a} = n, \ f(n) = n \log n \)

Only case 3 is possible, but \( \nexists \ r < 1 \) to make \( af(n/b) \leq rf(n) \) holds for all \( n \).

\[
af(n/b) - rf(n) = 2(n/2) \log(n/2) - rn \log n \\
= n(\log n - 1) - rn \log n \\
= (1 - r)n \log n - n > 0 \text{ if } r < 1
\]
Solving via Recursion Tree

\[
n \log n
\]

\[
\frac{n(\log n-1)}{2}
\]

\[
\frac{n(\log n-2)}{4}
\]

\[
\frac{n(\log n-2)}{4}
\]

\[
\frac{n(\log n-2)}{4}
\]

\[
\frac{n(\log n-2)}{4}
\]

\[
\ldots
dots
dots
\]

\[
n(\log n - k + 1)
\]
Summation

\[ T(n) = n \log n + n(\log n - 1) + n(\log n - 2) \]
\[ + \cdots + n(\log n - k + 1) \]
\[ = (n \log n) \log n - n(1 + 2 + \cdots + k - 1) \]
\[ = n \log^2 n - nk(k - 1)/2 \quad \text{//substitute with } k = \log n \]
\[ = \Theta(n \log^2 n) \]
